

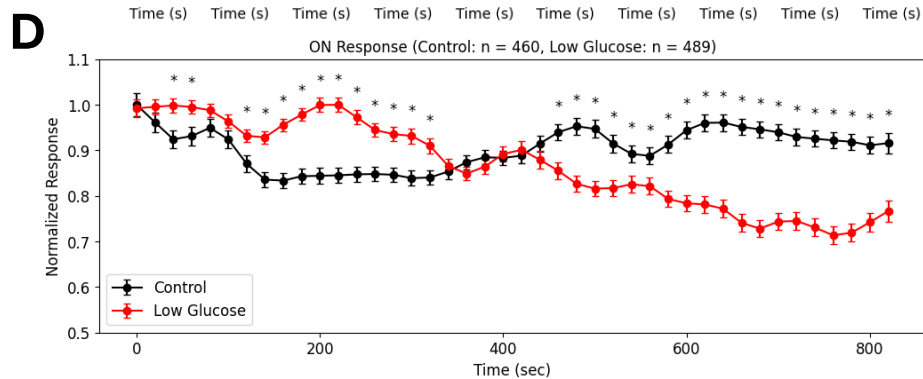

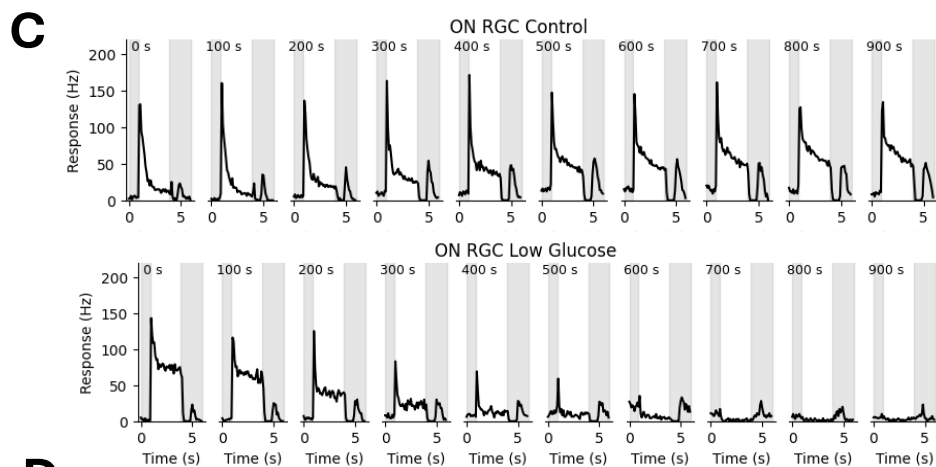

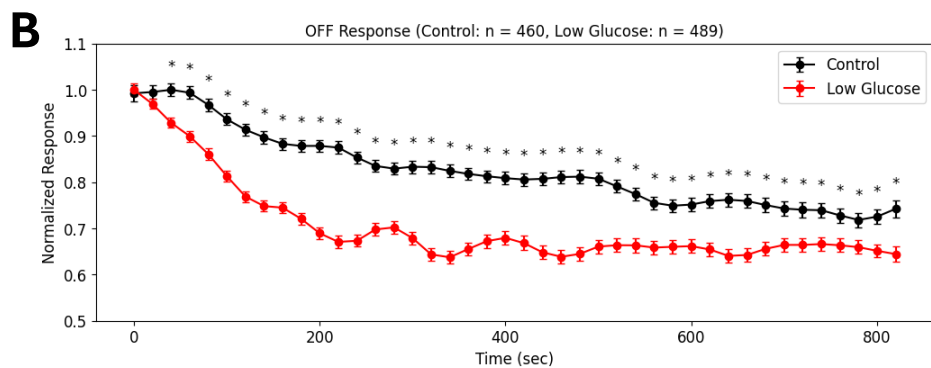

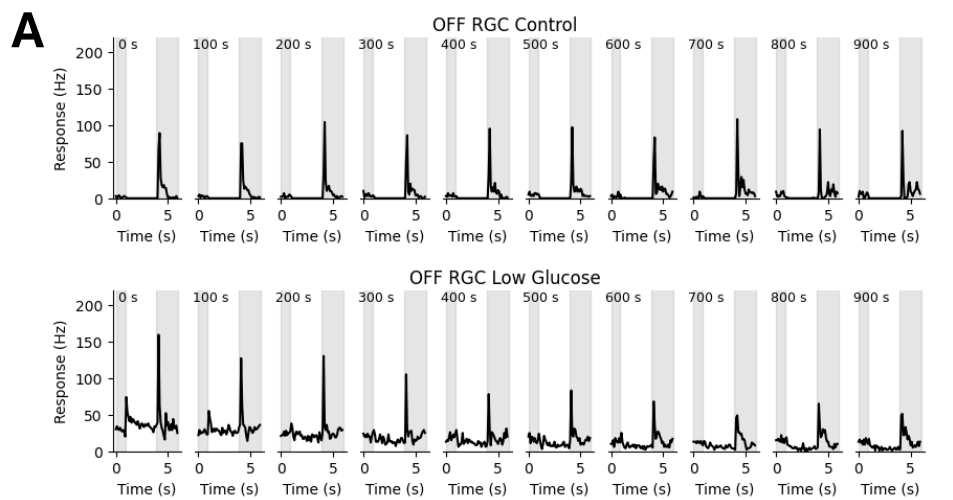

Figure X. Hypoglycemia accelerates the decay of light-evoked responses in retinal ganglion cells (RGCs).

(A) Representative OFF-RGC spike-rate traces recorded under control and low-glucose conditions. Gray shading indicates darkness; white shading indicates the 3-s light stimulus delivered every 10 s. Traces are averages of 10 repeats. **(B)** Population time course of OFF-RGC responses. For each cell, responses were normalized to its maximum amplitude and plotted as mean $\pm$ SEM over time (Control: n = 460 cells; Low glucose: n = 489 cells). Black, control; red, low glucose. **(C)** Representative ON-RGC traces recorded as in (A) under control and low-glucose conditions. **(D)** Population time course of ON-RGC responses, normalized and displayed as in (B) (Control: n = 460; Low glucose: n = 489). Black, control; red, low glucose. Asterisks indicate time points with significant differences between conditions ($p < 0.05$).
